Reflexes are automatic, subconscious response to changes within or outside the body.

a. Reflexes maintain homeostasis (Autonomic reflexes) – heart rate, breathing rate, blood pressure, and digestion

b. Reflexes also carry out the automatic action of swallowing, sneezing, coughing and vomiting.

c. Reflexes maintain balance & posture

ex. Spinal reflexes – control trunk and limb muscles.

d. Brain reflexes – involve reflex center in brain stem.

ex. Reflexes for eye movement
Reflex Arc

The reflex arc governs the operation of reflexes. Nerve impulses follow nerve pathways as they travel through the nervous system. The simplest of these pathways, including a few neurons, constitutes a reflex arc. Paths that pass through the spinal cord are called spinal reflexes.
Parts of Reflex Arc

1. **Receptor** – detects the stimulus
   
a) Description: the receptor end of a particular dendrite or a specialized receptor cell in a sensory organ.

b) Function: sensitive to a specific type of internal or external change.

2. **sensory neuron** – conveys the sensory into the brain or spinal cord.
   
a. Description: Dendrite, cell body, and axon of a sensory neuron.

b. Function: transmit nerve impulses from the receptor into the brain or spinal cord.
3. **Interneuron**: relay neurons.
   a. Description: Dendrite, cell body, and axon of a neuron within the brain or spinal cord.
   b. Function: serves as processing center, conducts nerve impulses from the sensory neuron to a motor neuron.

4. **Motor neuron**: conduct motor output to the periphery.
   a. Description: Dendrite, cell body, and axon of a motor neuron.
   b. Function: transmits nerve impulse from the brain or spinal cord out to an effector.
5. **Effecter**:

- **a. Description**: a muscle or gland.
- **b. function**: Response to stimulation by the motor neuron and produces the reflex or behavioral action.
- **monosynaptic stretch reflex**: 
  - simplest reflex because it has only one synapse in the path of its arc.
  - muscle spindles contain the sensory receptors for the stretch reflex.
  - Each spindle contains modified muscle fibers called spindle or intrafusel fibers (inside spindle), innervated by gamma efferent fibers.
• The middle segment of each spindle fiber acts as a mechanical stretch receptor that is connected to a sensory afferent nerve to the spinal cord.

• Stretching of the muscle stretches the spindle fibers activating the Ms stretch receptors and the associated sensory fibers.
Simple Receptors: Encapsulated

- The terminals of the spindle sensory fibers make direct excitatory synaptic contact with alpha motor neurons serving the ordinary muscle fiber (extrafusal fibers).

- Contraction of these fibers shorten the muscle and relaxes the spindle fibers terminating the stretch reflex and muscle contraction.
Events in monosynaptic stretch reflex

1. passive stretch of a muscle (produced by tapping its tendon) stretches the spindle (intrafusal) fibers.

2. stretching of a spindle distorts its central (chain) region, which stimulates dendritic endings of sensory nerves.

3. Action potentials are conducted by afferent (sensory) fibers into the spinal cord on the dorsal roots of spinal nerves.

4. Axons of sensory neurons synapse with dendrites and cell bodies of somatic motor neurons located in the ventral horn gray matter of the spinal cord.

5. Efferent impulses in the axons of somatic motor neurons (which form the ventral roots of the spinal nerves) are conducted to the ordinary (extrafusal) muscle fibers. These neurons are (alpha) motor neurons.
6. Release of Ach from the endings of alpha motor neuron stimulates the contraction of extrafusal fibers, and thus the whole muscle.

7. Contraction of the muscle relieves the stretch of its spindles, thus decreasing electrical activity in the afferent nerve fibers, and relaxes the spindle fiber and terminates the SR and muscle contraction.
The deep tendon Reflex

- If you tap on the tendon of a muscle, it contracts. Its synergists contract and its antagonists are inhibited.
- Poly synaptic reflex.
- A tap on the patellar tendon stretches the extensor muscle and its spindles.
- The spindle discharges and excites the associated sensory fibers that excite the motor neurons to the extensor muscle.
- Contraction of the extensor muscle extends the lower hey (knee-jerk).
- Ipsilateral flexor muscle relax for extensors to function.
- Branches of the sensory fibers from muscle spindle activate inhibitory interneuron, which in turn inhibit the motor neuron to the flexor muscle.
The withdrawal reflex (flexor reflex)

- The automatic withdrawal of an extremity from a painful stimulus.

- A polysynaptic reflex.

- Sensory pain signals excite motor neurons to the flexor muscles, eliciting flexion and withdrawal of the leg.

- Motor neurons to the extensor muscles are inhibited via inhibitory interneurons.

- This would relax the extensors of the same leg.
The withdrawal reflex

1. Painful stimulus activates nociceptor.
2. Primary sensory neuron enters spinal cord and diverges.
3a. One collateral activates ascending pathways for sensation (pain) and postural adjustment (shift in center of gravity).
3b. Withdrawal reflex pulls foot away from painful stimulus.
3c. Crossed extensor reflex supports body as weight shifts away from painful stimulus.
The crossed extensor reflex:

- A polysynaptic reflex.

- Ex. Painful stimulation of one foot causes flexion (withdrawal) of the ipsilateral leg as well as the extension of the contralateral leg, to stabilize the posture; thus the ipsilateral leg flexors are activated and the extensors are inhibited and vice versa in the contralateral leg.
Biceps jerk reflex: the examiner places finger on the inside of the extended elbow over the tendon of the biceps muscle and the finger is tapped. The biceps contracts in response, and the forearm flexes at the elbow.

Triceps jerk reflex: tapping the short tendon of the triceps muscle close to its insertion near the tip of the elbow elicit this reflex. The muscle contracts in response, and the forearm extends, slightly.

Abdominal reflex: the examiner strokes the skin of the abdomen with a dull pin from the side of abdomen upward towards the midline and above the umbilicus. The umbilicus moves towards the stimulated region.
- Ankle – jerk reflex (plantar reflex): tapping the Achilles tendon just above its insertion on the calcareous elicits this reflex. The response is plantar flexion, produced by contraction of the gastrocnemius and the solue muscles.

- Cremastric reflex: this reflex is elicited in males by stroking the upper inside of the thigh. In response, the testis on the same side is elevated by contracting muscles.
Clinical Terms:

- **Analgesia**: loss or reduction in the ability to sense pain, without loss of consciousness.

- **Analgesic**: pain-relieving drug.

- **Anesthesia**: loss of feeling.

- **Ataxia**: partial or complete inability to coordinate voluntary movements.

- **Epilepsy**: Disorders of the CNS that is characterized by temporary disturbances in normal brain impulses; it may be accompanied by convulsive seizures and loss of consciousness.
- **Huntington disease** – Hereditary disorders of the brain producing progressively worsening, uncontrollable dance like movements and personality changes.

- **Neuralgia** : sharp, recurring pain associated with a nerve, usually caused by inflammation or injury.
